ABSTRACT
A 11 years old German Shepherd bitch with the history of abdominal distension, vomiting, and purulent vaginal discharge was presented to Veterinary Clinical Complex, DUVASU, Mathura. Haematological examination revealed increase in total erythrocyte count and total leucocyte count while decrease in platelet count. The condition was treated with ovariohysterectomy and histopathological examination revealed the condition as cystic endometrial hyperplasia with pyometra complex.

Keywords: Bitch, Cystic, Endometrial Hyperplasia, Pyometra.

INTRODUCTION
Cystic Endometrial Hyperplasia (CEH) is a proliferative condition of female reproductive system involving abnormality in growth and repair of glandular epithelium of uterine endometrium and commonly observed in elderly female canines. It mainly involves cystic dilatation of endometrial glands causing abnormal accumulation of fluid in endometrial ands and lumen of uterus (Moxon et al., 2016, Sridevi et al., 2011). The exact pathogenesis of CEH is still unknown but according to current investigations the CEH – Pyometra complex occurs due to simultaneous influence of hormonal factors as well as infectious stimuli (Wozna-Wysocka et al., 2021). The progesterone hormone is responsible for hyperplasia of endometrium mainly the superficial epithelium, endometrial glands as well as secretory activity of endometrial glands (Agudelo, 2005; Corrada et al., 2006). The hyperplastic endometrium frequently gets inflammed and gets ascending bacterial infection from vagina that ultimately causes severe inflammation of uterus. This further progress into pyometra (filling of uterine lumen with purulent content), responsible for systemic clinical signs (Schlafer and Gifford, 2008).
CASE HISTORY AND OBSERVATIONS

An 11 years old German Shepherd bitch was presented to Veterinary Clinical Complex, DUVASU, Mathura with the history of abdominal distention, anorexia, polydipsia and vomiting with purulent vaginal discharge in last 10 days. There was no history of mating since last 4 years. On USG examination typical pockets of pyometra were found. Haemato-biochemical examination revealed increased total leucocyte count, total erythrocyte count, serum urea and serum creatinine while decrease in platelet count and serum albumin.

TREATMENT AND DISCUSSION

On the basis of gynaeco-clinical examination, ovariohysterectomy was performed as per standard procedure. Presence of multiple number of cysts of variable size on uterine endometrium along with metritis and necrosis in uterine horns were observed. The sample was sent for histopathological examination. The bitch was given systemic antibiotic therapy along with NSAID with supportive fluid therapy, proton pump inhibitors, healing stimulants and multivitamins for 7 days. The bitch recovered uneventfully within 15 days.

Gross morphology

**Fig. 1:** Enlarged uterine horns with presence of necrosis in left uterine horn and presence of multiple number of cysts of variable size along with necrosis in right uterine horn.

**Histopathological examination**

**Fig. 3:** Dilated, cystic endometrial glands of marked irregular size and shape as shown by asterisk and separated by abundant stroma. In some glands there is intra-luminal accumulation of neutrophils as shown by square. There is abundant peri glandular fibrosis as shown by triangle. H&E 100X.

**Fig. 2:** Magnified image of right uterine horn having multiple cysts in uterine endometrium along with purulent exudate filled in the lumen of uterine horn.

**Fig. 4:** Severe cystic dilatation of endometrial glands as shown by asterisk. H&E 200X.
Abnormality in sex hormones plays a key role in development of CEH (Bigliardi et al., 2004). The increase in plasma progesterone after ovulation promotes endometrial hyperplasia and provides an excellent medium for bacterial growth (Haji et al., 2017) and repeated progesterone stimulus leads to an exaggerated response in the uterus. This causes increased secretory activity of endometrial glands leading to hyperplasia of glands and accumulation of fluid in the endometrial glands as well as uterine lumen (De Bosschere et al., 2001) as observed in the present case. The progesterone also causes a decrease in myometrial contractibility. Thus, the change in the microenvironment of uterus and decreased contractibility make the condition favourable for ascending bacterial infection thus ultimately progressing into pyometra (Agudelo, 2005) which might be the reason for purulent vaginal discharge. Histopathological examination reveals inflammation and cystic condition of endometrial glands. Normalization of elevated plasma urea nitrogen, creatinine, transaminases and alkaline phosphatase as well as cholesterol after ovariohysterectomy suggested the surgical intervention as the ultimate treatment of the condition (Gupta et al., 2014).

CONCLUSION
The condition was diagnosed as CEH- Pyometra complex and successfully managed with ovariohysterectomy and antibiotic therapy. The bitch recovered without any complication.
